(54) Title: APPARATUS FOR DELIVERING ENDOLUMINAL PROSTHESIS AND METHODS FOR PREPARING SUCH APPARATUS FOR DELIVERY

(57) Abstract: A delivery apparatus (10) includes a tubular sheath (12) including proximal, intermediate (20), and distal (18) portions defining a lumen (16). A wall of the distal (18) portion is transparent, allowing observation of the lumen within the distal portion. The distal portion terminates in a rounded distal tip (14) including a plurality of leaflets (24). A self-expanding stent (50) is disposed within the intermediate portion (20), and a bumper member (30) is slidably disposed within the lumen (16) proximate the stent. Before use, the sheath (12) is retracted to bump the stent (50) forward into the distal portion until the stent (50) is observed within the distal portion (18). After the apparatus has been pre-loaded, the distal portion (18) is advanced into a blood vessel (100), e.g., across a stenosis (102), and the sheath (12) is retracted, causing the leaflets (24) to open and allow the stent (50) to be deployed, whereupon the stent (50) automatically expands to dilate the stenosis (102).

WO 03/090644 A1

APPARATUS FOR DELIVERING ENDOLUMINAL PROSTHESIS AND
METHODS FOR PREPARING SUCH APPARATUS FOR DELIVERY

FIELD OF THE INVENTION

5 The present invention relates generally to apparatus and methods for delivering endoluminal prostheses within body lumens of a patient, and more particularly to apparatus for delivering tubular prostheses or “stents” within a patient’s vasculature for treating stenoses or other lesions, for example, within the coronary and carotid arteries, and to methods for preparing such apparatus before insertion into a patient.

BACKGROUND

10 In recent years, a number of minimally invasive technologies have been developed for treating diseases, such as atherosclerosis, that result in narrowing of blood vessels, for example, within the coronary or carotid arteries. Tubular prostheses or “stents” have been developed for maintaining the patency of a blood vessel, for example, following angioplasty or other procedures used to treat a stenosis, occlusion, or other lesion within the blood vessel. The stent may be implanted across a treatment site to scaffold the site and prevent it from subsequently contracting or otherwise becoming obstructed.

15 Generally, the stent may be placed upon a catheter in a contracted condition, and the catheter advanced endoluminally to the treatment site until the stent is positioned across the stenosis. The stent may then be deployed and anchored at the treatment site. The stent may be self-expanding, i.e., may be biased to expand to an enlarged condition upon release from the delivery catheter, thereby automatically anchoring the stent at the treatment site.

20 Alternatively, the stent may be plastically deformable, i.e., may be expanded with the aid of a balloon that may underlie the stent on the catheter. The balloon may be inflated to expand the stent from the contracted condition to the enlarged condition to engage the wall of the treatment site. A balloon, for example, on a separate balloon catheter, may also be used to further expand and/or anchor a self-expanding stent.

25 Similarly, for ablation procedures and the like, a catheter including an array of electrodes, for example, on an expandable basket assembly, may be provided. The device may be introduced into a body lumen, e.g., through the patient’s vasculature into the heart, to treat conditions, such as heart arrhythmia.

30 With any of these devices, a sheath may be provided over the catheter to protect the elements on the distal end of the catheter, such as a stent, a balloon, and/or an array of

electrodes. The sheath may be advanced distally over the proximal end of the catheter until it covers the distal end and the element(s) thereon, or the distal end of the catheter may be introduced into the sheath, and advanced until it is proximate the distal end of the sheath. The distal end of the catheter, with the overlying sheath thereon, may then be introduced into a patient and positioned at a treatment site, whereupon the sheath may be retracted to expose the distal end of the catheter. After treatment, the sheath may be advanced back over the distal end of the catheter, and the entire device withdrawn from the patient.

One of the problems associated with these devices is that they may have substantially blunt distal ends that may scrape along the wall of a vessel during advancement therethrough, possibly damaging the wall and/or dislodging embolic material from the wall. To facilitate atraumatic advancement, particularly through tortuous anatomy, transition tips have been suggested for these devices.

For example, a conical or tapered nosepiece may be provided on the distal end of the catheter. A sheath may be disposed over the catheter, for example, to substantially cover the stent or other underlying element, such that the nosepiece extends distally from the end of the sheath, a distal edge of the sheath abutting the nosepiece. The nosepiece may facilitate advancement of the device through a narrow region of a blood vessel, although it may also risk catching on the wall of the vessel and/or dislodging embolic material, e.g., between the distal edge of the sheath and the nosepiece. Following delivery of a stent from the device, the nosepiece is generally positioned distal to the treated lesion. If the nosepiece is withdrawn directly, the proximal edge of the nosepiece may catch on the stent struts, resulting in the potential for trauma and embolic debris release. Alternatively, the sheath may be re-advanced across the treatment site to "recapture" the nosepiece, although in this approach the distal edge of the sheath may also catch on the stent struts.

As an alternative to a tapered nosepiece, a sheath having a rounded distal end has been suggested, as disclosed in U.S. Patent No. 5,593,412 issued to Martinez et al. Weakened areas or slits are provided in the distal end, thereby defining sections that may be softened upon introduction of warm saline solution. Once the sections are softened, the sheath may be retracted from an underlying balloon catheter to expose and implant a stent mounted on the catheter. Introduction of saline or other liquids into a patient's vasculature, however, may be undesirable, but is necessary in order to soften the sections on the distal end of the sheath and allow the stent to be deployed from the sheath.

Another problem associated with such delivery systems is that the sheaths and/or catheters may buckle during insertion, because of the distal force applied from the proximal

end to advance them through the patient's vasculature. In addition, because of their tubular nature, they may kink when advanced through tortuous anatomy, possibly damaging the device or an element within the device.

Another problem associated with self-expanding stents is the stent embedding within the delivery apparatus. With this type of stent, the delivery apparatus generally includes an overlying sheath that prevents the stent from expanding prematurely. A distal end of the delivery apparatus, with the sheath over the stent, may be introduced into a patient and positioned at a treatment site, whereupon the sheath may be retracted to expose the stent. The stent may then automatically expand to engage and/or open the treatment site.

During storage or otherwise before use), however, the stent may partially embed itself into a wall of the sheath. Because of its inherent bias to expand, the stent may exert an outward force on the sheath and, over time, cause the wall of the sheath to deform, creating a pocket within which the stent may nest. During use, the stent may resist being removed from this pocket, and "stick" to the sheath as the sheath is retracted at a treatment site within a patient's vasculature. Retraction of the sheath despite this may compress the stent axially, possibly crushing or damaging the stent within the lumen. Alternatively, as the stent is compressed axially, forces may build within the stent until they overcome the frictional engagement with the pocket, and cause the stent to spring distally out of the pocket. This may cause the stent to move unpredictably within the lumen, to be ejected from the lumen suddenly, or cause an unusual tactile feedback to the user, all of which may contribute to inaccurate delivery of the stent.

U.S. Patent No. 6,019,778, issued to Wilson et al., attempts to address this problem by providing a braided mesh within the wall of a sheath of a delivery apparatus. Because a stent is generally not a continuous smooth-walled tube, but may include many edges or corners, such a braided mesh may not prevent edges or corners of the stent from nesting into pockets between strands in the braided mesh. In addition, because reinforcing structures, such as the braided mesh of the Wilson et al. patent, are generally embedded within a wall of a sheath, the portion of the wall between the reinforcing structure and the stent may remain at risk of being deformed and creating a pocket.

Accordingly, it is believed that apparatus and methods for delivering a stent that may overcome some of these problems would be considered useful.

SUMMARY OF THE INVENTION

The present invention is directed to apparatus and methods for delivering treatment elements, such as tubular prostheses or “stents,” within a body lumen of a patient, for example, for treating stenoses or other lesions within the coronary arteries, the carotid arteries, or other blood vessels, and to methods for making such apparatus. The present invention is also directed to methods for preparing such apparatus before introduction into a patient, and to methods for using such apparatus to deliver prostheses or otherwise treat a patient.

In accordance with one aspect of the present invention, an apparatus is provided that includes an elongate tubular member having a proximal end, a distal end, and a lumen extending between the proximal and distal ends. The distal end has a size for insertion into a blood vessel and terminates in a substantially atraumatic distal portion including a plurality of flexible leaflets integrally molded thereto.

The leaflets are deflectable from a closed position wherein the leaflets engage one another to an open position wherein the leaflets define an opening communicating with the lumen. Preferably, the leaflets define a substantially rounded bullet shape in the closed position, although alternatively, the leaflets may define a substantially conical shape in the closed position. The leaflets are preferably substantially flexible and independently deflectable at a temperature less than body temperature, and are biased towards the closed position, but are resiliently deflectable to the open position. Adjacent leaflets may be separated by a slit, or may be connected to one another by weakened regions, the weakened regions being tearable upon retraction of the tubular member with respect to the prosthesis to allow the leaflets to be deflected towards the open position.

In a preferred embodiment, a tubular prosthesis is disposed within the lumen proximate the distal portion. An elongate bumper member having a proximal end and a distal end is also provided, the bumper member being slidably disposed within the lumen of the sheath. The distal end of the bumper member has a blunt edge disposed adjacent to the proximal end of the prosthesis for preventing axial displacement of the prosthesis upon retraction of the tubular member with respect to the bumper member and/or the prosthesis.

Preferably, the prosthesis comprises a self-expanding stent, such as a coiled-sheet stent, the stent being biased to assume an expanded condition having a cross-section larger than the lumen of the tubular member, and being compressible to a contracted condition to facilitate insertion into the lumen.

In accordance with another aspect of the present invention, an apparatus for delivering a prosthesis into a blood vessel of a patient is provided that includes an elongate tubular

member, such as that described above, having a proximal end, a distal end, and a lumen extending between the proximal and distal ends, the distal end having a size for endoluminal insertion into a blood vessel. A tubular prosthesis is disposed within the lumen proximate the distal end. An elongate bumper member is also provided that includes a helical coil having a proximal end and a distal end, the bumper member being slidably disposed within the lumen of the sheath. The distal end of the bumper member has a blunt distal edge disposed adjacent a proximal end of the prosthesis for preventing axial displacement of the prosthesis upon retraction of the tubular member with respect to the bumper member.

In a preferred embodiment, the bumper member includes a helical wire compression coil, preferably a solid height coil, extending between its proximal and distal ends. A plastic bumper element may extend from a distal end of the helical coil, the bumper element including the blunt distal edge thereon. An extension element may extend distally from the bumper element, the extension element having a cross-section substantially smaller than the bumper element, whereby the extension element may extend through the prosthesis disposed within the lumen of the tubular member. The helical coil, bumper element, and/or the extension element may include a lumen extending axially therethrough for receiving a guidewire therethrough.

In accordance with yet another aspect of the present invention, a method for making a sheath for delivering a treatment element within a body lumen of a patient is provided. A tubular member is provided that is formed from a substantially flexible material, the tubular member having a proximal end, a distal end, and a lumen extending axially between the proximal and distal ends, the distal end having a size for insertion into a body lumen. A die is provided having a bore therein, the bore having a tapered shape.

The die is heated to a temperature in excess of a melting point of the flexible material from which the tubular member is formed. The distal end of the tubular member is inserted into the bore of the heated die until a distal portion of the tubular member is softened and deformed into a tapered shape substantially enclosing the distal end. One or more slits are then created in the distal portion of the tubular member after it is deformed into the tapered shape, the slits defining a plurality of leaflets. A treatment element may be inserted into the lumen of the tubular member until it is disposed proximate the distal portion.

In a preferred method, a bullet having a tapered distal end is inserted into the distal end of the tubular member before inserting the distal end of the tubular member into the bore. Preferably, the bullet and the bore have corresponding substantially rounded shapes defining a mold cavity therebetween when the distal end of the tubular member is inserted into the bore.

In another preferred method, the treatment element is a tubular prosthesis for implantation within a body lumen of a patient. Preferably, the prosthesis is a self-expanding stent biased to assume an expanded condition having a cross-section larger than the lumen, and compressible to a contracted condition before being inserted into the lumen of the tubular member. The prosthesis may be inserted into the lumen of the tubular member before inserting the distal end of the tubular member into the bore, e.g., inserted into the lumen from the distal end of the tubular member. Alternatively, the prosthesis may be inserted into the lumen from the proximal end of the tubular member, e.g., either before or after the leaflets are formed on the distal portion of the tubular member.

An elongate bumper member may be inserted into the lumen of the tubular member, the bumper member being slidably disposed within the lumen of the tubular member, the distal end having a blunt distal edge for abutting a proximal end of the prosthesis. To make the bumper member, an elongate helical coil may be provided having a proximal end and a distal end. A tubular bumper element may be attached to the distal end of the helical coil to provide the bumper member, the bumper element including the blunt distal edge of the bumper element. Preferably, the bumper element is formed from plastic, and is attached to the helical coil by heating the bumper element until it is softened, and then directing the softened bumper element over the distal end of the helical coil. A tubular extension element may be attached to the bumper element, the extension element having a cross-section substantially smaller than the bumper element.

In accordance with yet another aspect of the present invention, an apparatus is provided for delivering a prosthesis into a body lumen of a patient. The apparatus includes a tubular member including a proximal portion, a distal portion having a size for insertion into a body lumen, and an intermediate portion between the proximal and distal portions. Each portion includes a wall defining a lumen extending between the proximal and distal portions. The wall of the distal portion may allow observation of the lumen within the distal portion, e.g., may be formed from substantially transparent material, and/or material free from reinforcing elements.

A prosthesis, preferably a self-expanding stent, is disposed within the tubular member proximal to the distal portion, and a bumper member is slidably disposed within the lumen of the tubular member. A distal end of the bumper member is disposed adjacent a proximal end of the prosthesis for preventing axial displacement of the prosthesis upon retraction of the tubular member. Thus, the prosthesis may be moved at least partially into the distal portion, whereupon the prosthesis may be observed through the wall of the distal portion.

Alternatively, the prosthesis may be disposed within the tubular member proximal to the distal portion, which may or may not be substantially transparent. The bumper member may be slidably disposed within the lumen of the tubular member, and an actuator may be coupled to the tubular member and the bumper member. The actuator, e.g., a handle device,
5 may be configured for retracting the tubular member relative to the bumper member a predetermined distance to pre-load the prosthesis, and/or to maintain the tubular member under tension when the tubular member is retracted.

Before using the apparatus, the tubular member may be retracted proximally with respect to the prosthesis to pre-load or "bump forward" the prosthesis. Retraction may be
10 ceased when at least a portion of the prosthesis is observed within the distal portion of the tubular member. For example, the tubular member may be retracted relative to the bumper member a distance equal to or greater than a length of the prosthesis. Thus, the prosthesis may be bumped forward to remove the prosthesis from a location where it has become nested or partially embedded within a wall of the tubular member. This may facilitate subsequent
15 movement of the tubular member relative to the prosthesis, i.e., allowing the prosthesis to slide freely within the lumen.

In addition, a proximal tension may be applied to the tubular member during retraction, thereby removing any substantial slack in the tubular member. The proximal tension may be maintained after retraction is ceased, thereby preventing any substantial slack from returning
20 into the tubular member.

After the apparatus has been pre-loaded, it may be used to deliver the prosthesis within a patient, e.g., within a body lumen, such as a carotid artery, cerebral artery, coronary artery, or other blood vessel. The distal portion of the tubular member may be introduced into the patient's body, e.g., percutaneously into a peripheral vessel, and advanced into a target body
25 lumen. The tubular member may be retracted to deploy the prosthesis from the apparatus and into the body lumen.

Upon deployment, the prosthesis preferably automatically expands to substantially engage tissue surrounding the body lumen and/or dilate a stenosis or other lesion within the body lumen. Alternatively or in addition, a balloon or other expandable member may be used
30 to further expand the prosthesis, e.g., to dilate a stenosis or otherwise anchor the prosthesis in place.

Other objects and features of the present invention will become apparent from consideration of the following description taken in conjunction with the accompanying drawings.

BRIEF DESCRIPTION OF DRAWINGS

FIG. 1A is a cross-sectional side view of a sheath having a rounded distal tip, in accordance with the present invention.

FIG. 1B is a cross-sectional side view of an apparatus for delivering a stent, including the sheath of FIG. 1A.

FIGS. 2A and 2B are end views of the sheath of FIGS. 1A and 1B, showing leaflets closed and partially open, respectively.

FIGS. 3A-3E are cross-sectional views showing a method for forming a rounded distal tip on a sheath, such as that shown in FIG. 1A.

FIGS. 4A and 4B are cross-sectional side views of the apparatus of FIGS. 1A and 1B, showing the stent being pre-loaded into the distal portion of the sheath, before delivery of the stent.

FIGS. 5A and 5B are cross-sectional views of a body lumen, showing a method for implanting a stent, in accordance with the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Turning now to the drawings, FIGS. 1A-2B show a preferred embodiment of an apparatus 10 for delivering a stent or other tubular prosthesis 50 into a blood vessel or other body lumen of a patient (not shown), in accordance with the present invention. Generally, the apparatus 10 includes an elongate tubular sheath 12 having a proximal end (not shown), a distal end 14, and a lumen 16 extending generally therebetween. The tubular sheath 12 may be formed from a substantially flexible or semi-rigid material that may facilitate its advancement within a body lumen of a patient, preferably within the vasculature of a patient.

For example, the sheath 12 may be formed from a polymer, such as pebax, polyethylene, urethane, nylon, or other plastic material, that may be extruded or molded into elongate tubing of a desired length. Preferably, the tubing has a wall thickness of between about 0.003-0.006 inch (0.075-0.150 mm), and has a substantially uniform outer diameter appropriate for the size of the stent being implanted, for example, between about 1.5-2.5 mm. The sheath 12 may have a substantially uniform construction along its length, or the sheath 12 may include portions along its length having varying degrees of flexibility.

In a preferred embodiment, the sheath 12 includes a distal portion 18 formed entirely from a substantially flexible material, such as pebax. Preferably, the distal portion 18 is formed from a material that allows observation of the lumen 16 within the distal portion 18. For example, the distal portion 18 is formed from substantially transparent pebax, that may be

free from reinforcing elements, thereby facilitating direct visual observation through the wall of the distal portion 18 into the lumen 16.

The sheath 12 also includes an intermediate portion 20 formed from pebax including a reinforcing or stiffening element 20 therein. For example, the intermediate portion 20 may include a braid or mesh, e.g., of stainless steel, laid over a Teflon liner, with pebax tubing formed over the braid. Alternatively, the reinforcing element 22 may be a helical wire coil and the like molded or otherwise formed in the tubing. The reinforcing element 22 may enhance a rigidity of the intermediate portion 20, for example, to reduce the risk of the intermediate portion 20 buckling or kinking, while still providing flexibility transverse to the longitudinal axis 28, e.g., to accommodate advancement through tortuous anatomy. The intermediate portion 20 may be translucent or substantially opaque. Alternatively, the intermediate portion 20 may be substantially transparent and one or more visual markers (not shown) may be provided on the intermediate portion 20 and/or the distal portion 18 to facilitate pre-loading of the stent 50.

Preferably, the sheath 12 also includes a proximal portion (not shown) that is formed from a more rigid material, such as nylon tubing, that may include a stiffening element as described above. The distal portion 18 may have a length of between about ten and twenty centimeters (10-20 cm), the intermediate portion 20 may have a length of between about twenty and thirty centimeters (20-30 cm), and the proximal portion may have a length of between about eight five and one hundred twenty centimeters (85-120 cm), preferably about one hundred centimeters (100 cm) or more.

The distal portion 18 of the sheath 12 preferably has a rounded bullet shape defined by a plurality of flexible leaflets 24 that are integrally formed thereon. The leaflets 24 are preferably deflectable from a closed position, wherein adjacent leaflets 24 abut one another, to an open position. In the closed position, the leaflets 24 substantially close the lumen 16, as shown in FIG. 2A. Preferably, in the closed position, the leaflets 24 define a relatively small opening 25 where their apices meet. In the open position (the leaflets 24 are shown only partially open in FIG. 2B), the leaflets 24 are spread apart to define an opening 26 communicating with the lumen 16. Preferably, in the open position, the leaflets 24 are oriented substantially axially such that the opening 26 has a cross-section similar to the lumen 16. In the preferred embodiment shown in FIGS. 2A and 2B, three leaflets 24 are provided, although additional leaflets may be provided if desired.

As best seen in FIG. 1A, in the closed position, the leaflets 24 preferably define a substantially atraumatic distal portion 18 that may facilitate advancement of the sheath 12

endoluminally within a patient's vasculature with minimal risk of dislodging embolic material from and/or otherwise damaging the wall of a body lumen through which the sheath 12 is advanced. In the preferred embodiment shown, the leaflets 24 define a substantially rounded bullet shape in the closed position. Alternatively, leaflets 24 defining a substantially conical shape (not shown) in the closed position may be provided, with the leaflets 24 preferably biased to the closed position, as described below.

The leaflets 24 are substantially flexible and independently deflectable substantially independent of the temperature to which the leaflets 24 are exposed, e.g., at a temperature substantially less than body temperature. In a preferred embodiment, the leaflets 24 are biased towards the closed position, but are resiliently deflectable to the open position. This may ensure that the opening 26 remains substantially closed until time of deployment of an element, such as stent 50, from within the lumen 16, and/or that the leaflets 24 do not catch on anything and open inadvertently. This may be particularly important when the apparatus 10 is advanced through tortuous anatomy, as described further below. Alternatively, the leaflets 24 may be at least partially plastically deformed when they are deflected from the closed position to the open position. In this alternative, the leaflets 24 may not return completely to the closed position when released from the fully open position, e.g., after the stent 50 is deployed from the apparatus 10.

Preferably, adjacent leaflets 24 are separated by a relatively narrow slit 28, although alternatively, the leaflets 24 may partially overlap with one another in the closed position. In a further alternative, adjacent leaflets may be separated by a thin-walled or weakened region (not shown) that may be easily tearable upon retraction of the sheath 12 with respect to a stent or other element being deployed from within the lumen 16. Once the weakened regions are torn, the leaflets may be freely deflected towards the open position as the element is being deployed.

In addition, the leaflets 24 may have a thickness that is substantially thinner than a wall thickness of the rest of the distal portion 18, preferably tapering towards their distal tips 24a as shown in FIGS. 1A and 1B, thereby enhancing the flexibility of the leaflets 24. The tapering thickness may also ensure that the leaflets 24 are biased towards the closed position, yet may deflect easily to accommodate a guidewire (not shown), bumper extension element, and the like, as described further below.

Returning to FIG. 1B, in a preferred embodiment, the apparatus 10 also includes an elongate bumper member 30 that is slidably disposed within the sheath 12. The bumper member 30 preferably includes a proximal end (not shown), a distal end 32, and a lumen 34

that extends therebetween. The bumper member 30 preferably has a substantially uniform outer diameter slightly smaller than the interior lumen 16 of the sheath 12, preferably by about 0.003-0.005 inch (0.075-0.125 mm) to create a close sliding, but not interfering, fit between the bumper member 30 and the sheath 12. The lumen 34 has a diameter sufficiently large to accommodate a guidewire (not shown) therethrough, preferably between about 0.015-0.020 inch (0.375-0.500 mm), and more preferably about 0.016 inch (0.400 mm).

In a preferred form, the bumper member 30 is formed from a helical wire compression coil 36, e.g., having adjacent turns that substantially abut one another. The coil 36 may be formed from flat or round wire, e.g., of stainless steel and the like, that is continuously helically wound along the length of the bumper member 30, preferably a solid height coil. A relatively thin layer of Teflon 38 and the like may be provided around the outside of the coil 36 to enhance a sliding relationship between the bumper member 30 and the sheath 12. Because of the coil 36, the bumper member 30 may be substantially resistant to buckling or kinking, while facilitating bending of the bumper member 30 transverse to the longitudinal axis 28.

A substantially rigid tubular segment (not shown) may be attached to or otherwise extend from the proximal end of the coil 36. Preferably, the tubular segment is a section of hypotube having an inner lumen (not shown) similar to the lumen 34 of the coil 36, and more preferably a two-stage length of hypotube that has a greater outer diameter on its proximal-most end. The tubular segment may facilitate distal advancement of the bumper member 30 into the sheath 12 with minimal risk of buckling and/or may provide enhanced tactile perception of relative movement of the bumper member 30 and the sheath 12. A valve or other seal (not shown), e.g., for accommodating a guidewire therethrough while maintaining a fluid-tight seal, may also be provided on the proximal end of the tubular segment.

The bumper member 30 also includes a tubular bumper element 40 on a distal end 37 of the coil 36 that includes a substantially blunt distal edge 42. The bumper element 40 is preferably formed from pebax or other plastic material. A plastic bumper element 40 ensures no metal-to-metal contact, e.g., between the coil 36 of the bumper member 30 and the stent 50 that may lead to corrosion of the stent material. In addition, pebax and other substantially flexible materials may deform slightly, e.g., when the sheath 12 is retracted, to enhance contact between the blunt distal edge 42 of the bumper element 40 and the stent 50. The bumper element 40 is preferably attached to the distal end 37 of the coil 36, e.g., by heating the bumper element 40 to soften it and directing it over the distal end 37, such that the bumper element is fused into the coils adjacent the distal end 37.

Alternatively, the bumper element 40 may be eliminated and the distal end 37 may be substantially blunt to abut the stent 50. If metal-to-metal contact is to be avoided, the distal end 37 may be coated with an inert film or coating (not shown).

5 The bumper member 30 may also include a radiopaque or other marker 48 thereon for identifying a location of the bumper member 30 using external imaging, such as fluoroscopy. Preferably, a platinum iridium ring 48 is provided on the bumper element 40 immediately adjacent the blunt distal edge 42, thereby identifying a position of the proximal end 52 of the stent 50. Alternatively, a marker (not shown) may be provided elsewhere on the apparatus 10 in addition to or instead of the marker 48, such as on the sheath 12 or the stent 50 itself. Thus, 10 the marker 48 may facilitate positioning of the apparatus 10, and more particularly the stent 50 or other element therein, axially within a body lumen (not shown) before deploying the element from within the sheath 12, as described further below.

The bumper member 30 may also include a tubular extension element 44 that is thermally bonded or otherwise attached to and extends distally from the bumper element 40. 15 The extension element 44 has an outer diameter that is substantially smaller than the bumper element 40. For example, the extension element 44 may be partially inserted into the bumper element 40 as it is thermally bonded thereto so as not to interfere with the blunt edge 42 of the bumper element 40. Preferably, the extension element 44 has an outer diameter of about 0.66 mm (0.026 inch) to facilitate its insertion through the stent 50, an inner diameter of about 0.41 20 mm (0.016 inch) to accommodate a guidewire therethrough, and a length of about 25 mm (1.0 inch). The extension element 44 may be appropriately sized larger or smaller to accommodate a guidewire, for example, between about 0.009-0.038 in (0.225-0.95 mm). The extension element 44 is preferably substantially flexible, e.g., providing little or no structural integrity, and has a substantially smooth outer surface to provide a low-friction, sliding contact with an 25 element disposed within the sheath 12.

In a preferred embodiment, a stent 50 or other tubular prosthesis or graft may be disposed within the lumen 16 of the sheath 12 proximate the distal portion 18. The stent 50 preferably is expandable between a contracted condition that facilitates its loading into the lumen 16 of the sheath 12, and an enlarged condition for engaging a wall of a blood vessel or 30 other body lumen (not shown). In a preferred embodiment, the stent 50 is a coiled-sheet stent, such as that disclosed in U.S. Patent No. 5,443,400 issued to Sigwart, and/or in co-pending applications Serial Nos. 09/347,845, filed July 2, 1999, and 09/406,984, filed September 28, 1999, the disclosures of which are incorporated herein by reference. Preferably, the stent 50 is self-expanding, i.e., may be biased to assume the enlarged condition, but may be compressed

and constrained in the contracted condition, for example, by the lumen 16 of the sheath 12. Alternatively, the stent 50 may be plastically deformable, i.e., may be substantially relaxed in the contracted condition, but may be forcibly expanded to the enlarged condition, for example, using a balloon catheter, as is known in the art.

5 Generally, the apparatus 10 is provided pre-assembled with the stent 50 disposed within the lumen 16 of the sheath 12 adjacent the distal portion 18 of the sheath in its contracted condition. Preferably, the stent 50 is provided proximally to the distal portion 18, e.g., such that the stent 50 is located entirely within the intermediate portion 20. More preferably, the stent 50 has a length, L, and is disposed at a distance equal to or greater than
10 the length, L, from the distal end 14 of the sheath 12, explained further below.

 The bumper member 30 is also disposed within the lumen 16 such that the blunt edge 42 of the bumper element 40 is adjacent a proximal end 52 of the stent 50. The extension element 44 preferably extends distally through the stent 50 and through the leaflets 24, as best seen in FIGS. 1B and 2B. The extension element 44 may facilitate insertion of a guidewire
15 (not shown) through the apparatus 10, i.e., through the lumen 16 of the sheath 12 into the lumen 34 of the bumper member 30 to a proximal end of the apparatus 10. Preferably, the opening 25 at the apices of the leaflets 24 accommodates the extension element 44 therethrough without causing the leaflets 24 to partially buckle or bulge.

 Alternatively, the extension element 44 may be eliminated, either alone or along with
20 the bumper element 40. In these alternatives, the distal end 37 of the coil 36 may include an inlet port (not shown) communicating with the lumen 34, e.g., for backloading a guidewire (not shown) into the lumen 34, as explained further below.

 The apparatus 10 may be used to implant the stent 50 within a body lumen, preferably within a carotid artery, a coronary artery, a cerebral artery, a renal artery, or other blood
25 vessel, as described further below. In a further alternative, the apparatus 10 may incorporate “rapid exchange” configurations where a guidewire may exit from the lumens 16, 34 of the sheath 12 and/or bumper member 30 through side ports (not shown) at a location along their lengths, i.e., at an intermediate location, rather than at their proximal ends, as is known to those skilled in the art. To accommodate a guidewire between the sheath 12 and the bumper
30 member 30 during retraction, a longitudinal slot (not shown) may be provided in either the inner surface of the sheath or the outer surface of the bumper adjacent the side ports.

 Turning to FIGS. 3A-3E, a method is shown for forming a rounded bullet-shaped distal portion 18 on a tubular sheath 12 and the like. A tubular sheath 12 is provided that is formed from substantially flexible plastic material, such as those described above, preferably

transparent pebax, and that has a lumen 16 therein extending from the distal end 14 towards the proximal end (not shown). The sheath 12 initially has a distal end 14 that terminates in a substantially blunt distal edge 19 (FIG. 3A).

5 In a preferred embodiment, the sheath 12 has a plurality of segments having varying degrees of flexibility, for example, including a distal portion 18, an intermediate portion 20, and a proximal portion (not shown). Preferably, the distal portion 18 is a predetermined length of substantially transparent pebax tubing that is thermal bonded, e.g., butt bonded to the intermediate portion, which is a predetermined length of pebax tubing reinforced by a stainless steel braid, such as the lengths described above. The intermediate portion 20, in turn, is
10 thermally bonded to a predetermined length of nylon tubing. Alternatively, an adhesive, connectors, and the like may be used to attach two or more of the portions to one another, in addition to or instead of butt bonding.

Preferably, the sheath 12 is pre-assembled, i.e., with the distal portion 18, intermediate portion 20, and proximal portion bonded to one another before the distal portion 18 is formed
15 into its bullet shape, as described below. Alternatively, the distal portion 18 may be formed into its bullet shape and/or other steps of the method performed before the distal portion 18 is attached to the intermediate portion 20.

A stent 50 or other prosthesis may be disposed within the lumen 16, preferably a predetermined distance greater than the length, L, of the stent 50 from the distal end 14 of the
20 sheath 12. Preferably, the stent 50 is constrained in its contracted condition, and inserted into the distal end 14 of the sheath 12 before the distal portion 18 is formed into its bullet shape. Alternatively, the stent 50 may be provided in its contracted condition, and introduced into the lumen 16 from the proximal end of the sheath 12, e.g., either before or after the distal portion 18 is formed into its bullet shape.

25 In a preferred embodiment, the stent 50 is a self-expanding tubular member formed from Nitinol having a transition temperature between ambient and body temperatures. The stent 50 may be formed into its enlarged condition in its austenitic phase (e.g. by hand rolling for a coiled-sheet stent) and heat treated to set the enlarged condition in its shape memory. The stent 50 may then be chilled to its martensitic phase, e.g., at a temperature below ambient
30 temperature, and preferably between about 0-10 degrees Celsius, or lower, for example, by blowing liquid Nitrogen onto the stent 50.

The stent 50 may then be pulled through one or more draw-down fixtures, i.e., tapered tubular dies (not shown), which may be chilled, to plastically compress the stent 50 into a contracted condition. In the contracted condition, the stent 50 preferably has a diameter

substantially smaller than the lumen 16 of the sheath 12. The stent 50 may then be pulled from the draw-down fixture into the lumen 16 of the sheath 12. In a preferred method, a Teflon tubular guide or sheath (not shown) may be used to facilitate sliding the stent 50 through one or more of the draw-down fixtures. The stent 50 may be pulled into the Teflon guide as it enters a draw-down fixture, the Teflon guide being split or otherwise removed from the stent 50 before it is pulled into the sheath 12.

The bumper member 30 (not shown in FIGS. 3A-3C) may be inserted into the lumen 16 of the sheath 12 until the extension element 44 approaches, but does not extend from, the distal end 14 of the sheath 12. For example, the blunt edge 42 of the bumper element 40 may abut the proximal end 52 of the stent 50, with the extension element 44 extending therethrough. Alternatively, the bumper member 30 may not be extended distally to abut the stent 50 until after the distal portion 18 is formed into its bullet shape. In a further alternative, the bumper member 30 may not be introduced into the sheath 12 until after the distal portion 18 is formed into its bullet shape.

Returning to FIGS. 3A-3C, a die 60, e.g., a spherically shaped "hot die," is provided having a bore or other recess 62 therein. The bore 62 has an entry 64 with a cross-section substantially similar to the cross-section of the sheath 12, a rounded inner end 66 having a tapered shape corresponding to the desired shape of the rounded distal portion 18 (FIG. 3C), and a relatively narrow aperture 67 extending distally from the inner end 66 through the die 60. The die 60 may be coupled to a heating element in a conventional manner such that the die 60 may be heated to a desired temperature, as is well known in the art. In a preferred method, the die 60 is heated to a temperature in excess of a melting point of the material from which the distal portion 18 of the sheath 12 is formed, for example, between about 150-200 degrees Celsius (about 300-400 degrees Fahrenheit), and preferably about 160 degrees Celsius (320 degrees Fahrenheit).

As seen in FIG. 3A, a bullet 70 may be inserted a predetermined distance into the distal end 14 of the sheath 12, i.e., such that the bullet 70 does not contact the stent 50 (shown in FIG. 3B) but provides sufficient sheath material beyond a distal end 72 of the bullet 70 to form the bullet-shaped distal portion 18. Preferably, a wire or other filament 73 is attached to the bullet 70 that extends distally from the distal end 72 of the bullet 70. The bullet 70 and die 60 may be formed from like materials, preferably a hardened and polished tool steel. The distal end 72 of the bullet 70 may have a predetermined curved shape corresponding to the rounded inner end 66 of the bore 62 in the die 60.

In preparation for molding the distal portion 18 of the sheath 12, the filament 73 may be guided through the aperture 67, maintaining sufficient tension to keep the filament 73 taut, but without pulling the bullet 70 from the tubular member 12. As shown in FIG. 3B, the distal portion 18 of the tubular member 12 may be inserted into the bore 62 of the heated die 60 until
5 the distal portion 18 of the tubular member 12 is softened and deformed to fill the cavity defined between the distal end 72 of the bullet 70 and the rounded inner end 66 of the bore 62.

Thus, the distal portion 18 may be molded into a rounded bullet shape, the molded shape being defined by the distal end 72 of the bullet 70 and the rounded inner end 66 of the bore 62 in the die 60. Preferably, only slight pressure, e.g., mere hand pressure, preferably
10 between about one to two pounds (1-2 lbs.), is applied axially to the sheath 12 to fill the cavity defined by the bullet 70 and the bore 62 and ensure that there are no discontinuities in the resulting bullet shaped distal portion 18. Because of the filament 73, the resulting bullet shaped distal portion 18 may include the relatively small opening 25 (not shown in FIG. 3B) therethrough corresponding to the filament 73 for accommodating a guidewire or bumper
15 extension element (not shown).

As shown in FIG. 3C, once the rounded bullet-shaped distal portion 18 is formed, the sheath 12 may be removed from the bore 62 of the die 60, and allowed to cool for sufficient time to substantially solidify the sheath, i.e., to return to its flexible, but solid state.

One or more slits 34 (not shown, see FIG. 2A) may then be formed in the tapered
20 region 19 of the distal portion 18. Preferably, a cutting device (not shown) is used that includes three cutting wires or blades that are equally spaced radially about a central axis. The cutting device may be aligned with the longitudinal axis 28 of the sheath 12 and forced into the enclosed distal portion 18 until the cutting device cuts completely through the material of the enclosed distal portion 18. The cutting device may then be withdrawn, thereby providing a
25 plurality of substantially independently flexible leaflets 24 (not shown, see FIG. 2A) on the distal portion 18.

As shown in FIGS. 3D, the bullet 70 may be removed from the distal portion 18, e.g., by pulling on the filament 73 to deflect the leaflets 24 and withdraw the bullet 70 through the opening 26. The leaflets 24 preferably resiliently return to their closed position upon removal
30 of the bullet 70, as shown in FIG. 3E, thereby defining the opening 25.

Alternatively, the filament 73 and aperture 67 may be eliminated from the bullet 70 and die 60, and the bullet 70 withdrawn from the formed sheath 12 using other methods. For even numbers of symmetrical slits, a cutting device including a single blade or wire (not shown) may be oriented substantially perpendicular to the longitudinal axis 28 of the sheath

12, and a plurality of individual transverse slits may be cut into the distal portion 18. In alternative methods, individual leaflets may be formed using a multi-cavity tool, and the leaflets may be shaped into a final position, as will be appreciated by those skilled in the art.

Once the leaflets 24 are formed, the bumper member 30 may be advanced further
5 distally to push the stent 50 into a desired position within the lumen 16 of the sheath 12, as shown in FIG. 3E (in which the bumper element 40 and extension element 44 have been eliminated for convenience). The stent 50 may be positioned proximate the bullet-shaped distal portion 18, and/or the extension element 44 (not shown) may be extended through the stent 50 and through the opening 25. Preferably, during this stage, the stent 50 remains
10 entirely within the intermediate portion 20, but may be in close proximity to the distal portion 18 of the sheath 12. Alternatively, the intermediate portion 20 may be formed from substantially transparent material, and may include markers (not shown) for providing visual indicators of the proper position for the stent 50. The apparatus 10 may then be packaged, shipped, or otherwise provided to users to introduce and implant the stent 50 within a
15 body lumen of a patient, as described further below.

In an alternative method, the stent 50 may be inserted into the sheath 12 from its proximal end after the distal portion 18 is formed into its bullet shape. For example, the stent 50 may be constrained in its contracted condition, and advancing it through the lumen 16 of the tubular member 12 to the distal portion 18. The stent may be released, i.e., unconstrained,
20 once introduced into the lumen 16, whereupon the stent may partially expand to engage the wall of the lumen 16. Preferably, the stent remains slidable within the lumen 16 such that the stent 50 may be advanced to a location proximate the distal portion 18 and/or easily deployed through the opening 26. The bumper member 30 may be inserted into the proximal end of the sheath 12 and directed distally to advance the stent 50 to the desired position.

Turning to FIGS. 4A-5B, the apparatus 10 may be used to implant the stent 50 or other prosthesis within a body lumen 100 of a patient, such as within a coronary, carotid, cerebral, renal artery, or other blood vessel. Initially, the apparatus 10 may be stored in a configuration as shown in FIG. 4A, e.g., during shipping or other pre-use handling. In this storage
25 configuration, the stent 50 may be disposed entirely within the intermediate portion 20, i.e., such that the distal end 54 of the stent 50 is located proximal to the distal portion 18 of the sheath 12, as described above.
30

As is shown in FIG. 4A, due its bias to expand, the stent 50 may partially embed itself into the sheath 12, creating a pocket 17, even though the intermediate portion 20 may include a reinforcing element 22, such as a braid or mesh. To remove the stent 50 from this pocket 17,

the sheath 12 may be retracted relative to the bumper member 30. The distal end 34 of the bumper member 30 holds the stent 50 and prevents it from being displaced proximally along with the sheath 12. Consequently, the stent 50 may be directed into the distal portion 18 of the sheath 12, as shown in FIG. 4B.

5 Preferably, because of the substantially transparent material of the distal portion 18, entry of the stent 50 into the distal portion 18 may be directly observed through the wall of the distal portion 18. More preferably, the sheath 12 is retracted a distance equal to or greater than the length, L, of the stent 50, thereby ensuring that the stent 50 is removed entirely from the pocket 17. This may ensure that subsequent retraction of the sheath 12 allows the stent 50 to
10 freely slide along the inner wall of the sheath 12.

If the distal end 54 of the stent 50 is initially disposed immediately adjacent to the distal portion 18, the sheath 12 may be retracted until the entire stent 50 is observed within the distal portion 18. Alternatively, the distal end 54 of the stent 50 may be initially disposed a distance equal to or greater than its length, L, from the distal portion 18. In this case, the
15 sheath 12 may be retracted until the distal end 54 of the stent 50 is observed entering the distal portion 18. In a further alternative, if the distal portion 18 is not substantially transparent, the sheath 12 may be retracted a predetermined distance equal to or greater than the length, L, which may be monitored from the proximal end (not shown) of the apparatus 10.

To facilitate retracting the sheath 12, a handle device (not shown) may be coupled to
20 the proximal ends (not shown) of the sheath 12 and the bumper member 30. The handle device may include an actuator mechanism (also not shown) for moving the sheath 12 axially relative to the bumper member. Preferably, the actuator mechanism only allows the sheath 12 to be retracted proximally and does not allow the sheath 12 to be returned distally relative to the bumper member 30. Such a device is disclosed in co-pending application Serial No.
25 09/613,872, filed July 10, 2000, the disclosure of which is expressly incorporated herein by reference.

Such a handle device and/or actuator mechanism may maintain a constant tension on the sheath 12, e.g., for eliminating any slack or backlash that may be encountered due to slight longitudinal elasticity of the sheath 12. In addition, such a uni-directional device may prevent
30 the sheath 12 from being advanced over the bumper member after delivery of the stent 50.

Turning to FIGS. 5A and 5B, once the stent 50 is pre-loaded to a desired position, the apparatus 10 may be percutaneously introduced into the patient's vasculature. For example, the distal portion 18 may be introduced into a peripheral vessel, such as a femoral or carotid artery (not shown) and advanced endoluminally to a target treatment region 102, e.g., within a

carotid, cerebral, or coronary artery. Preferably, the apparatus 10 is advanced over a guidewire 104 already placed across the treatment region 102 using conventional methods. The guidewire 104 may be backloaded through the extension element 44, and through the bumper member 30 to the proximal end (not shown) of the apparatus 10, as described above.

5 The rounded distal portion 18 of the sheath 12 substantially protects the stent 50 during advancement and/or allows atraumatic advancement of the apparatus 10. Preferably, as explained above, the leaflets 24 are resiliently flexible and biased to the closed position, causing the leaflets 24 to hug the guidewire 104 during advancement, particularly through tortuous anatomy. For example, if the leaflets 24 are flexible and biased to the closed position,
10 the leaflet(s) 24 on the outside of a sharp bend may hug the guidewire 104, rather than deflecting away from the guidewire 104 and risking catching on the wall of the vessel, and possibly damaging the wall and/or dislodging embolic material from the wall. In addition, the rounded distal portion 18 may facilitate advancement of the apparatus 10 through the treatment region 100.

15 Once the apparatus 10 is advanced into the body lumen 100, the stent 50 may be positioned across the treatment region 102, as shown in FIG. 5A, for example, by monitoring the marker 48 using fluoroscopy and the like. Preferably, the treatment region 102 is a stenotic or occluded region of a blood vessel, although other lesions or damaged vessel segments may be treated, as will be appreciated by those skilled in the art.

20 Once the stent 50 is properly positioned, the bumper member 30 may be held stationary, and the sheath 12 retracted to deploy the stent 50 from the lumen 16, as shown in FIG. 5B. Because of their flexible nature, the leaflets 24 easily deflect outward to allow the stent 50 to be deployed through the opening 26, and slide over the stent 50 and/or over the bumper member 30. Once the stent 50 is deployed, the apparatus 10 may be withdrawn from
25 the body lumen 100 and from the patient (not shown). The sheath 12 may remain in its retracted position without requiring advancement back over the bumper element 40 and/or the extension element 44 before removing the apparatus 10. The leaflets 24 preferably hug the outside of the bumper member 30, thereby facilitating substantially atraumatic withdrawal of the apparatus 10.

30 Preferably, the stent 50 is self-expanding, and therefore automatically expands upon deployment to engage the body lumen 100 at the treatment location 102. The stent 50 may trap embolic material between itself and the body lumen 100 and/or may dilate and hold the body lumen 100 open. If desired to further expand the stent 50, an expansion device, such as a catheter (not shown) may be introduced into the body lumen 100, e.g., upon removal of the

apparatus 10, and positioned within the stent 50. A balloon or other expandable member (also not shown) on the catheter may be expanded to engage and further expand the stent 50 to a predetermined diameter, e.g., corresponding substantially to the unobstructed diameter of the body lumen 100.

5 In an alternative embodiment (not shown), the stent 50 may be plastically expandable, and may be mounted onto a catheter that is inserted into a sheath 12 in accordance with the present invention. The catheter may include a balloon or other expandable member over which the stent may be mounted. Once the sheath is retracted to deploy the stent, for example, at a target treatment region, the expandable member may be expanded, e.g., by inflating the
10 balloon, to plastically deform the stent and expand it to engage the body lumen at the treatment region. Once the stent has been expanded to a desired size, the expandable member may be deflated, and the apparatus withdrawn from the body lumen and the patient.

In further alternatives, other deployable devices may be provided within a sheath in accordance with the present invention, such as an electrode device, e.g., an array of electrodes
15 on an expandable basket assembly and the like. Once a desired location is reached, such as a chamber of a heart, the sheath may be retracted with respect to the underlying device, until one or more elements on the device are deployed from the sheath. A procedure may be completed at the location, e.g., an ablation procedure, and then the sheath and device may be withdrawn from the location.

20 While the invention is susceptible to various modifications, and alternative forms, specific examples thereof have been shown in the drawings and are herein described in detail. It should be understood, however, that the invention is not to be limited to the particular forms or methods disclosed, but to the contrary, the invention is to cover all modifications, equivalents and alternatives falling within the spirit and scope of the appended claims.

WHAT IS CLAIMED IS:

1. An apparatus for delivering a prosthesis into a body lumen of a patient, comprising:

a tubular member comprising a proximal portion, a distal portion having a size for insertion into a body lumen, and an intermediate portion between the proximal and distal portions, each portion comprising a wall defining a lumen extending between the proximal and distal portions, the wall of the distal portion comprising material allowing observation of the lumen within the distal portion;

a prosthesis disposed within the tubular member proximal to the distal portion; and

a bumper member comprising a proximal end and a distal end, the bumper member being slidably disposed within the lumen of the tubular member, the distal end being disposed adjacent a proximal end of the prosthesis for preventing axial displacement of the prosthesis upon retraction of the tubular member such that the prosthesis may be moved at least partially into the distal portion, whereupon the prosthesis may be observed through the wall of the distal portion.

2. The apparatus of claim 1, wherein the prosthesis comprises a stent biased to assume an expanded condition having a cross-section larger than the lumen of the tubular member, and being compressible to a contracted condition to facilitate insertion into the lumen.

3. The apparatus of claim 1, wherein the prosthesis is disposed entirely within the intermediate portion of the tubular member until the tubular member is retracted relative to the bumper member.

4. The apparatus of claim 1, wherein the intermediate portion of the tubular member is substantially opaque.

5. The apparatus of claim 1, wherein the intermediate portion of the tubular member is translucent.

6. The apparatus of claim 1, wherein the intermediate portion of the tubular member comprises a reinforcing element.

7. The apparatus of claim 1, wherein the distal portion is substantially transparent.

8. The apparatus of claim 1, wherein the distal portion is free from reinforcing elements.

9. The apparatus of claim 1, wherein the distal portion terminates in a distal tip having a rounded bullet shape.

10. The apparatus of claim 9, wherein the distal tip comprises a plurality of leaflets that are deflectable from a closed position, wherein adjacent leaflets abut one another, to an open position, for delivering the prosthesis from the lumen.

11. An apparatus for delivering a prosthesis into a body lumen of a patient, comprising:

a tubular member comprising a proximal portion, a distal portion having a size for insertion into a body lumen, and an intermediate portion between the proximal and distal portions, each portion comprising a wall defining a lumen extending between the proximal and distal portions, the wall of the distal portion comprising material allowing observation of the lumen within the distal portion;

a self-expanding prosthesis disposed within the tubular member proximal to the distal portion;

a bumper member comprising a proximal end and a distal end, the bumper member being slidably disposed within the lumen of the tubular member, the distal end being disposed adjacent a proximal end of the prosthesis for preventing axial displacement of the prosthesis upon retraction of the tubular member such that the tubular member may be retracted until at least a portion of the prosthesis is observed through the distal portion; and

an actuator coupled to the tubular member and the bumper member, the actuator configured for retracting the tubular member relative to the bumper member, the actuator maintaining the tubular member under tension when the tubular member is retracted.

12. The apparatus of claim 11, wherein the actuator comprises a handle device coupled to the proximal portion of the tubular member and the proximal end of the bumper member.

13. The apparatus of claim 11, wherein the prosthesis is disposed entirely within the intermediate portion of the tubular member until the tubular member is retracted relative to the bumper member.

14. The apparatus of claim 11, wherein the intermediate portion of the tubular member is substantially opaque.

15. The apparatus of claim 11, wherein the intermediate portion of the tubular member is translucent.

16. The apparatus of claim 11, wherein the intermediate portion of the tubular member comprises a reinforcing element.

17. The apparatus of claim 11, wherein the distal portion is substantially transparent.

18. The apparatus of claim 11, wherein the distal portion is free from reinforcing elements.

19. The apparatus of claim 11, wherein the distal portion terminates in a distal tip having a rounded bullet shape, the distal tip comprising a plurality of leaflets that are deflectable from a closed position, wherein adjacent leaflets abut one another, to an open position, for delivering the prosthesis from the lumen.

20. A method for preparing a delivery apparatus comprising a tubular member comprising a distal portion having a size for insertion into a body lumen, the distal portion comprising material allowing observation of a lumen of the tubular member within the distal portion, and a prosthesis disposed within the lumen proximal to the distal portion, the method comprising:

retracting the tubular member proximally with respect to the prosthesis; and

ceasing retraction when at least a portion of the prosthesis is observed within the distal portion of the tubular member.

21. The method of claim 20, wherein the prosthesis comprises a self-expanding stent having a length, and wherein the tubular member is retracted a distance equal to or greater than the length of the stent.

22. The method of claim 20, wherein the retracting step comprises applying a proximal tension to the tubular member, thereby removing any substantial slack in the tubular member.

23. The method of claim 22, further comprising maintaining a proximal tension applied to the tubular member after retraction is ceased, thereby preventing any substantial slack from returning into the tubular member.

24. The method of claim 20, wherein the tubular member comprises a substantially opaque or translucent portion proximal to the distal portion, and wherein the prosthesis is initially disposed entirely within the substantially opaque or translucent portion before the tubular member is retracted.

25. The method of claim 20, wherein the delivery apparatus further comprises a bumper member slidably disposed within the lumen adjacent the prosthesis, and wherein the retracting step comprises retracting the tubular member relative to the bumper member, the bumper member for preventing axial displacement of the prosthesis while the tubular member is retracted.

26. The method of claim 20, wherein the distal portion is substantially transparent.

27. A method for preparing a delivery apparatus comprising a tubular member comprising a lumen extending between proximal and distal portions, the distal portion having a size for insertion into a body lumen, and a prosthesis defining a length disposed within the lumen proximal to the distal portion, the method comprising:

retracting the tubular member proximally with respect to the prosthesis; and

ceasing retraction when the tubular member has moved a distance at least as long as the length of the prosthesis but before the prosthesis has emerged from a distal tip of the distal portion.

28. The method of claim 27, wherein the retracting step comprises applying a proximal tension to the tubular member, thereby removing any substantial slack in the tubular member.

29. The method of claim 28, further comprising maintaining a proximal tension applied to the tubular member after retraction is ceased, thereby preventing any substantial slack from returning into the tubular member.

30. The method of claim 27, wherein the distal portion comprises a material allowing observation of the lumen within the distal portion, wherein the tubular member comprises a substantially opaque or translucent portion proximal to the distal portion, and wherein the prosthesis is initially disposed entirely within the substantially opaque or translucent portion until the tubular member is retracted.

31. The method of claim 30, wherein retraction of the tubular member is ceased when at least a portion of the prosthesis is observed entering the distal portion.

32. The method of claim 27, wherein the delivery apparatus further comprises a bumper member slidably disposed within the lumen adjacent the prosthesis, and wherein the retracting step comprises retracting the tubular member relative to the bumper member, the bumper member for preventing axial displacement of the prosthesis while the tubular member is retracted.

33. A method for delivering a prosthesis into a body lumen of a patient using a delivery apparatus comprising a tubular member including a distal portion comprising material allowing observation of a lumen of the tubular member within the distal portion, and a prosthesis disposed within the lumen proximal to the distal portion, the method comprising:

retracting the tubular member initially relative to the prosthesis;

ceasing retraction when at least a portion of the prosthesis is observed within the distal portion of the tubular member;

advancing the distal portion of the tubular member into the body lumen;

retracting the tubular member further to eject the prosthesis from the lumen and into the body lumen.

34. The method of claim 33, wherein the prosthesis comprises a self-expanding stent, and wherein the stent automatically expands upon being ejected from the lumen to substantially engage tissue surrounding the body lumen.

35. The method of claim 33, wherein the initial retracting step comprises applying a proximal tension to the tubular member, thereby removing any substantial slack in the tubular member.

36. The method of claim 35, further comprising maintaining a proximal tension applied to the tubular member after retraction is ceased, thereby preventing any substantial slack from returning into the tubular member.

37. The method of claim 34, wherein the tubular member comprises a substantially opaque or translucent portion proximal to the distal portion, and wherein the prosthesis is initially disposed entirely within the substantially opaque or translucent portion until the tubular member is retracted during the initial retracting step.

38. The method of claim 33, wherein the delivery apparatus further comprises a bumper member slidably disposed within the lumen adjacent the prosthesis, and wherein the retracting steps comprises retracting the tubular member relative to the bumper member, the bumper member for preventing axial displacement of the prosthesis while the tubular member is retracted.

39. The method of claim 33, wherein the distal portion of the tubular member terminates in a distal tip comprising a plurality of leaflets, and wherein during the further retracting step, the prosthesis deflects the leaflets from a closed position to an open position to allow the prosthesis to be ejected from the lumen.

INTERNATIONAL SEARCH REPORT

Internatl	Application No
PCT/US	03/09838

A. CLASSIFICATION OF SUBJECT MATTER
IPC 7 A61F2/06

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 7 A61F

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

- *T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- *X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- *Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- *&* document member of the same patent family

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US 03/09838

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.: 33-39
because they relate to subject matter not required to be searched by this Authority, namely:
Rule 39.1(iv) PCT - Method for treatment of the human or animal body by surgery
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
☐ No protest accompanied the payment of additional search fees.
